INVESTOR IN PEOPLE

WIPO The Patent Office  
Concept House  
Cardiff Road  
Newport  
South Wales  
NP10 8QQ

10/523074

I, the undersigned, being an officer duly authorised in accordance with Section 74(1) and (4) of the Deregulation & Contracting Out Act 1994, to sign and issue certificates on behalf of the Comptroller-General, hereby certify that annexed hereto is a true copy of the documents as originally filed in connection with the patent application identified therein.

I also certify that the attached copy of the request for grant of a Patent (Form 1/77) bears an amendment, effected by this office, following a request by the applicant and agreed to by the Comptroller-General.

In accordance with the Patents (Companies Re-registration) Rules 1982, if a company named in this certificate and any accompanying documents has re-registered under the Companies Act 1980 with the same name as that with which it was registered immediately before re-registration save for the substitution as, or inclusion as, the last part of the name of the words "public limited company" or their equivalents in Welsh, references to the name of the company in this certificate and any accompanying documents shall be treated as references to the name with which it is so re-registered.

In accordance with the rules, the words "public limited company" may be replaced by p.l.c., plc, P.L.C. or PLC.

Re-registration under the Companies Act does not constitute a new legal entity but merely subjects the company to certain additional company law rules.

### Warning

After an application for a patent has been filed, the Comptroller of the Patent Office will consider whether publication or communication of the invention should be prohibited or restricted under Section 22 of the Patents Act 1977. You will be informed if it is necessary to prohibit or restrict your invention in this way. Furthermore, if you live in the United Kingdom, Section 23 of the Patents Act 1977 stops you from applying for a patent abroad without first getting written permission from the Patent Office unless an application has been filed at least 6 weeks beforehand in the United Kingdom for a patent for the same invention and either no direction prohibiting publication or communication has been given, or any such direction has been revoked.

### Notes

- If you need help to fill in this form or you have any questions, please contact the Patent Office on 08459 500505.
- Write your answers in capital letters using black ink or you may type them.
- If there is not enough space for all the relevant details on any part of this form, please continue on a separate sheet of paper and write "see continuation sheet" in the relevant part(s). Any continuation sheet should be attached to this form.
- If you have answered 'Yes' Patents Form 7/77 will need to be filed.
- Once you have filled in the form you must remember to sign and date it.
- For details of the fee and ways to pay please contact the Patent Office.

## Method for Surface Treatment of Clay, Ceramic or Cementitious Articles

This invention relates to a method for the surface treatment of clay, ceramic or cementitious articles, particularly roofing, floor and wall tiles, roofing panels  
5 and wall cladding panels, work tops and paving blocks. The method increases the smoothness, and can increase the density and hardness, of surfaces of such articles, thereby producing a glaze effect and increasing resistance to water penetration and to mould, moss or algae growth.

### 10 Background to the invention

Tiles for flooring, roofing or wall cladding are commonly made from clay or concrete, but can also be made from cement paste with a high loading of fibres, especially glass fibres. The latter are often formed as panels, larger in  
15 area than normal roofing tiles of clay or concrete.

Concrete tiles are produced in an extrusion process, wherein an extrudable, concrete mass is extruded as a ribbon and is passed through elements of the manufacturing apparatus which press, mould and cut the sheet into individual  
20 roofing tile format. Clay tiles are usually produced in a pressing process, the clay mass being pressed into moulds to form and shape the tiles. After extrusion or pressing, the tiles are then hardened, usually by accelerated curing methods involving heat and/or vacuum.

The surfaces of conventionally produced tiles tend to be somewhat rough,  
25 porous, and susceptible to scratching, especially in the case of concrete tiles. Surface porosity is undesirable because it affects the surface smoothness and results in water penetration, which carries an increased risk of degradation of the tile in freeze-thaw conditions, and makes the surface susceptible to moss, mould and algae growth, which is unsightly, and in the case of moss can lead  
30 to degradation of the tile. The surfaces of the tile are vulnerable to these adverse effects of water deposited on the weather exposed surface through rainfall, humidity, fog and the like, and on the interior facing surfaces through condensation. To reduce the roughness and porosity and to improve the

appearance of the tiles they are often glazed by either applying silicate frits to the surface and firing at high temperature or by painting with a hardenable lacquer prior to curing.

- 5 It would therefore be desirable to improve tile processing to reduce surface roughness and porosity, and to impart a glazed appearance to the tiles without the necessity and additional expense of a separate lacquering step. Other articles of clay, and concrete, for example pipes, guttering, ornamental panelling, kitchen worktops, paving blocks and the like would also benefit from  
10 such processing improvement. Ceramic articles too, such as wall and floor tiles could also benefit.

### **Brief description of the invention**

- The present invention makes available a method for improving surface  
15 smoothness, and in many cases the surface density and hardness, of clay, ceramic and cementitious articles, by applying a paste layer to the surface of the hardened or unhardened article, covering the paste layer with a smooth membrane or plate, and optionally vibrating the paste layer through the membrane or plate. The membrane or plate is separated from the paste layer  
20 prior to or after partial or substantially complete hardening. The optional surface vibration step has the effect of modifying the packing characteristics of the particles at the surface of the paste layer, increasing the density, and homogeneity of particles in the paste layer, to a depth which varies according to the composition of the paste, and the frequency, amplitude and duration of  
25 the vibration.

### **Detailed description of the invention**

- According to the invention, there is provided a method for the surface  
treatment of a clay, ceramic or cementitious article comprising  
30

(i) providing a hardened or partially hardened clay, ceramic or cementitious article, or a hardenable, water-containing clay, ceramic or cementitious mass shaped in the form of the article,

(ii) spreading a layer of eventually hardenable paste over a surface area of the article or shaped mass to be treated, the paste comprising at least first and second populations of particles co-dispersed in a water-containing phase, the second population being sufficiently small to pack the interstices between particles of the first population with which it is co-dispersed, at least one of the first and second populations being of reactive binder particles,

(iii) covering a surface area of the paste layer with a (a) a flexible membrane or (b) a plate or (c) first a flexible membrane then superimposed thereon a plate, the plate or membrane having an upper-surface and a smooth under-surface, such that in cases (a) and (c) the smooth membrane undersurface, and in case (b) the smooth plate undersurface, is in intimate contact with and conforms to the contours of that surface area of the paste layer, thereby providing a membrane-covered or plate-covered area of the paste layer,

(iv) optionally vibrating the membrane-covered or plate-covered area of the paste layer, such that vibration is transmitted through the membrane or plate, to the paste layer, and

(v) either removing the membrane, plate or plate and membrane then hardening the paste layer on the article or shaped mass, or at least partially hardening the paste layer on the article or shaped mass with the membrane, plate or plate and membrane in place.

#### *The Article or Mass to be Surface Treated*

The method of the invention is applied to a hardened or partially hardened clay, ceramic or cementitious article, or to hardenable, water-containing clay, ceramic or cementitious mass shaped in the form of the desired article. The article may be pressed or otherwise moulded from clay or ceramics material, or formed from a cementitious mass such as concrete or fibre-loaded cement paste by extrusion, rolling, pressing or a combination of such techniques. The water content of the mass to be treated by the method of the invention is not critical, but is preferably as low as possible, consistent with the shaping and

handling requirements of the particular article. Clay and cementitious articles are hardenable at ambient or elevated temperatures, or by microwave irradiation. Ceramic articles are hardenable by firing at high temperatures. Articles to which the invention is particularly applicable include, floor, wall and roofing tiles, as well as roofing and wall cladding panels, work-tops, paving blocks, and drainage pipes.

In the case of concrete tiles, especially roofing tiles, the shaped mass to which the method of the invention is applied will normally be provided by the pre-curing production stages of a conventional tile production process. In such processes, a mouldable, eventually hardenable mass comprising at least water and reactive binder particles, the latter including at least cement particles, is extruded from an extrusion orifice onto conveyor means adapted to carry the extruded mass as a ribbon away from the extrusion orifice. The ribbon has a lower surface in contact with the conveyor means and an upper surface, and is passed under a compacting and smoothing plate (known as a "slipper" or "glitter"), the lower surface of which contacts the upper surface of the ribbon across its width as it is conveyed under the plate by the conveyor means. The plate is positioned such that the extruded ribbon is pinched between the lower plate surface and the conveyor means as it passes under the plate, thereby compacting the ribbon and smoothing its upper surface as it slides in contact with the lower plate surface. The pressed, smoothed ribbon is then cut across its width into individual tile format. Usually, the conveyor means is a conveyor belt provided with a plurality of longitudinally closely adjacent pallets or moulds of individual tile dimensions onto which the ribbon is extruded, and the ribbon is cut into individual tiles across its width between adjacent pallets of moulds.

As is described in more detail below, the paste layer may be applied as step (ii) of the invention to the extruded tile ribbon or to the individual tiles cut from the ribbon

The method of the invention can be applied to conventional concrete tile mixes, based on cement particles, sand and water. However, good results are

often obtained when the composition also includes microsilica, fly ash or furnace slag powder (ground granulated blastfurnace slag), whose incorporation into the mix may be aided by a surfactant or plasticiser. Fibres of steel, glass or plastics material such as polyethylene may also be included.

5 Best results will generally be obtained when the particle sizes of the cement, sand and microsilica are selected for dense packing, for example where the sand has a volume average particle size in the range 0.1 mm to 10 mm (or where two or more grades of sand are used, each grade has a volume average particle size in that range) and the microsilica powder has a volume  
10 average particle size in the range 0.001  $\mu\text{m}$  to 100  $\mu\text{m}$ , (or where two or more grades of microsilica are used, each grade has a volume average particle size in that range). Fibres of length 3 mm to 100 mm are useful for increasing toughness.

### 15 *The Paste*

As used herein the term "paste " means a spreadable composition which has sufficient viscosity to remain in place on the article for the duration of the method of the invention after being spread thereon as a layer, without to any significant extent flowing off or pooling on the surface of the article. Pastes  
20 therefore may have the consistency of a thick lacquer, slurry, grout, mortar, or dough. The method of spreading the paste as a layer on the article will depend on its consistency and workability. In many cases, it will be possible to spray the paste on the article to the required layer thickness, or deposit the layer by passing the article through a falling curtain of paste. In other cases, it  
25 will be spreadable by means of a spreading tool, as a mortar layer is applied with a trowel. In other cases, the paste may be spread by pressure applied to individual portion(s) of paste deposited on the article, for example by pressing the flexible membrane or plate onto the paste portions by means of a roller, thereby squeezing them as a layer between the membrane or plate and the  
30 article. In yet other cases, paste carried on a rotating roller may be spattered from the roller onto the article by a brush which rotates in contact with the roller-carried.

The thickness of the paste layer on the article is not critical and may vary according to the size of the article, the composition of the paste, and the wear characteristics desired in the finished product. In general, the layer will be from 0.1 mm to 3 mm.

The eventually hardenable paste comprises at least first and second populations of particles co-dispersed in a water-containing phase, the second population being sufficiently small to pack the interstices between particles of the first population with which it is co-dispersed. The first population may have a weight average particle size in the range  $1\mu\text{m}$  to  $200\mu\text{m}$  and the second population may have number average particle size from  $0.001\mu\text{m}$  to  $20\mu\text{m}$ .

At least one of the first and second particle populations must be of reactive binder particles, i.e. particles which bind to one another during the paste hardening process, for example cement, fly ash, microsilica or blastfurnace slag particles which bind via hydration products. However, other particle-binding mechanisms exist, for example covalent cross-linking of polymer particles, and such binder particles and mechanisms may be used for specialized applications of the method of the invention.

In many cases, the first particle population will be of binder particles, and the second of binder or non-binder particles. In these case, the first particle population may be of cement, fly ash, or blastfurnace slag particles, with cement being preferred, and the second population may be of microsilica binder particles or non-binder particles such as iron oxide. However, the case where the first population is of non-binder particles such as micro-aggregate sand particles, and the second is of binder particles such as microfine cement or microsilica is also useable in the method of the invention.

The second particle population packs the interstices between particles of the first particle population. Because of such packing, the surface of the hardened paste has the potential for low porosity, smoothness, and high density. The use of a flexible membrane or plate, and optional vibrational treatment, in accordance with the invention encourages the development of those features. To further maximize the potential smoothness of the paste surface layer, it is desirable that the past should be mixed under conditions which minimize entrained air bubbles, or that the paste should be degassed, prior to spreading on the article.

The paste includes as a minimum, the first and second particle populations discussed above. However there is in principle no reason why more than two particle size populations should not be present in the paste. For example there might be a first population of binder particles, a second population of binder or non-binder particles capable of packing the interstices between the first particles, and a third binder or non-binder particle population capable of packing the interstices between the combined first and second populations. A population of small, for example from 100 $\mu$ m to 250 $\mu$ m, aggregate particles for example of silica or carborundum sand may be included in the paste, and/or a population of small fibres, for example of polymer such as polyethylene or polypropylene, or of glass or steel. All populations of particles and fibres present in the composition should preferably be well mixed and as near homogeneously dispersed as possible. The paste may also include biologically active agents, such as herbicidal, antifungal or antimicrobial agents to provide additional protection against the growth of moss, algae, or mould.

The surface of the article or shaped mass to which the paste layer is applied is advantageously rough and porous, to encourage good adhesion to the paste layer. If the article or shaped mass is a concrete tile manufactured via a normal tile production sequence as described above, even after the slipper or glitter step the surface is normally sufficiently rough and porous to permit good paste layer adhesion, but that step may sometimes be omitted. Alternatively,

the surface of the article or shaped mass may be roughened or primed with an adhesion aid prior to spreading the paste layer.

### 5 *The Membrane and Plate*

Membranes suitable for covering the surface of the paste layer should be flexible, so that they may be laid in intimate contact with and conforming to the contours of the area of the paste layer on the surface of the article which it is to cover. For the same reason, suitable plates should, have a smooth  
 10 contoured under-surface. Air bubbles between the membrane or plate and the paste layer are preferably avoided, as are wrinkles in the membrane. Generally, membranes should be laid as a skin on the area of paste layer to be covered. Thus, membranes may be rolled onto a pre-spread paste layer, or portion(s) of paste may be deposited on the article spread by the act of rolling  
 15 a membrane, or pressing a plate, into contact with the paste portions, thus spreading the paste layer on the article.

The under-surface of the membrane or plate in contact with the surface of the paste layer should be smooth, since the surface smoothness of the article  
 20 after the method of the invention is in part a function of intimate contact with the membrane or plate under-surface. The optional vibration step causes the particles in the surface of the paste layer to be agitated into increasingly intimate contact with the membrane or plate under-surface, so that the surface characteristics of the article mirror those of the membrane undersurface to a  
 25 large extent.

Preferably, the membrane or plate has low adhesion affinity for the paste layer, so that they may eventually be peeled or otherwise separated from that layer, which has preferably been hardened or partially hardened, without  
 30 significant damage to the paste layer surface. Flexible, smooth membranes for use in the invention include plastics films, for example of polyethylene or polypropylene, but in some cases paper based sheets, optionally with polymer coatings, or metal foils such as aluminium may be suitable. Plates for use in the invention include plastics plates, for example of acrylic resin materials,

and metal plates such as steel plate. The undersurface of the plate may be polished, or coated or plated with a bright metal, for example by vapour deposition or electrodeposition, to improve surface smoothness. The hardening process for the paste layer, and the article itself if not pre-

5 hardened, may involve heating in an oven, and in such cases it will of course be desirable to choose a membrane or plate material which is compatible with the hardening temperature and duration, or to separate the membrane from the paste layer prior to exposure to the hardening temperature.

10 In some cases it may be desirable to carry out the method of the invention by first laying a flexible membrane over the paste layer, then superimposing a plate on the membrane. For example, when the optional vibration step is employed, it may be preferable to use either a plate alone or a plate superimposed on a membrane, since transmission of vibration through a plate  
15 via a vibrating head may be less likely to wrinkle the membrane.

In the method of the invention, a relief-pattern may be formed on the smooth under-surface of the membrane or plate, such that when the membrane or plate covers and contacts the paste layer the relief pattern impresses the  
20 surface paste layer. Where a flexible membrane covers the paste layer the relief-pattern may be impressed on the paste layer by a tool, for example a roller, pressed into contact with the upper surface of the membrane. Where a flexible membrane covers the paste layer and a plate is superimposed thereon, and the under-surface of the plate has a relief-pattern formed  
25 thereon, a corresponding relief pattern is impressed on the paste layer through the membrane by pressing the plate into contact with the upper surface of the flexible membrane. Similar results are achieved by interposing a relief pattern between the membrane and the superimposed plate, in which case of course the under-surface of the plate need not be figured.

30

For tile production, the surface to be treated in accordance with the invention will normally be the upper surface, i.e. the surface which is visible when the tile is in use, although the invention can also be applied on both surfaces of the tile if required. For example where the normal tile production process

described above is employed, the base of the moulds on the conveyor belt may serve as a plate or may be lined with the desired membrane, and paste may be deposited on the mould or on the membrane in the mould. As the ribbon is accommodated in the mould, the paste in the mould may be spread  
 5 as a layer on the underside of the tile. For roofing tiles, the bottom edge of the tile is also visible, and the surface of that edge may benefit from treatment. Hence, plates may be shaped, and membranes may be cut to a size, such that they least cover the upper tile surface and extend over the edge of the tile to contact the bottom edge surface.

10

In a production process, the individual membrane or plate covers may be dispensed onto the tiles from a stockpile. A membrane may also be dispensed from continuous stock stored on a roller, rolled onto the tiles, tile ribbon or cut tile forms, then cut to the required individual tile size when in position covering  
 15 the ribbon (for example as the ribbon is cut into individual tile forms) or covering the individual tiles or tile forms.

#### *Optional Surface Vibration Through the Membrane and/or Plate*

When the method of the invention is implemented using a smooth membrane  
 20 in intimate contact with the paste layer, the paste layer may be vibrated through the membrane by pressing into intimate contact an area of the membrane-covered area of the paste layer and a membrane-contact surface of a vibratable plate element contoured to match that of the membrane-covered area of the paste layer, and causing the vibratable plate element to  
 25 vibrate while maintaining pressure contact between it and the membrane-covered area of the paste layer, such that vibration is transmitted from the vibratable plate element, through the membrane, to the surface of the article. Thereafter contact between the vibratable plate element and the membrane-covered surface of the paste layer is broken and the membrane is removed  
 30 or, preferably, the paste layer is at least partially hardened with the membrane in place.

---

When the method of the invention is implemented using a smooth plate in intimate contact with the paste layer, the paste layer may be vibrated through

the plate by pressing a vibrating head element into intimate contact with an area of the plate-covered area of the paste layer, and causing the head element to vibrate while maintaining pressure contact between it and the plate-covered area of paste layer, such that vibration is transmitted through the plate element to the paste layer. Thereafter contact between the head element and the plate-covered surface of the article is broken and the plate is separated from the paste layer or, preferably, the paste layer is at least partially hardened with the plate in place.

The vibratable plate element in contact with the membrane, or the smooth plate in contact with the paste layer, is conveniently of sheet metal, contoured to match the contours of the area of paste layer which it covers. Such a sheet metal plate may be vibrated by contacting a vibrating head element with the side of the plate opposite to the paste layer, and if necessary causing relative movement between the head element and the contacted plate, such that the vibrating head element traverses a desired area of that side. Since most tiles are rectangular in configuration, the vibratable plate element, or of course the smooth plate, may also be rectangular with uniform transverse cross sectional profile, matching the contours of the upper tile surface. In such cases, the vibrating head element may be contoured to match that profile, and the head may be caused to move longitudinally relative to the plate.

The axis or main axis of vibration of the plate may be perpendicular to the plane of the plate, but the vibration may also have components in other directions. Surface improvements are often obtained when vibration of a frequency of at least 150 Hz is transmitted from the plate element to the surface of the article. However, the frequency, amplitude and duration of the vibration may vary within wide ranges. Optimum parameters will be selected according to such factors as the composition of the paste layer being treated; the depth to which it is desired to influence the paste layer; the degree of surface glaze required on the finished article; and whether the production process for the article is a batch process or a continuous process. Good surface effects are often obtained when the plate is vibrated at ultrasonic frequencies, for example in the range 15 kHz to 50 kHz, or 15 kHz to 30 kHz,

or using a combination of first mechanical vibration for example in the range of 100 Hz to 800 and then vibration at ultrasonic frequency. The amplitude of vibration of the vibratable plate may be in the range 1 mm to 3 $\mu$ m. In one embodiment of the invention, the vibratable plate is alternately vibrated at two or more different frequencies and/or amplitudes.

As foreshadowed above, the frequency and amplitude of the vibration of the vibratable plate and the duration of the vibration may be selected to increase the surface density of the paste layer, relative to its density prior to vibration, to a depth of at least 10%, 25%, 50% or all of its thickness.

In the case of the continuous production of concrete tiles referred to above, i.e. by extrusion as a ribbon onto moulds carried on a conveyor belt, followed by cutting between moulds into individual tile format, the speed of production is conventionally relatively high, for example of the order of 100-150 tiles per minute. While continuous membrane sheet may be dispensed from a roller to cover the paste layer on the cut or uncut tile ribbon at those speeds, the speed of a single cycle of individual membrane or plate application and/or optional vibrational surface treatment may be too slow to be performed on each tile sequentially on a single conveyor belt. Hence, in one embodiment of the invention, the conveyor means divides into a plurality of tracks after the ribbon is cut into individual tiles. Tiles queued on the conveyer are successively transported onto separate tracks for the application of individual membrane or plate covers and/or optional vibrational treatment on each tile at individual stations associated with each track. The tracks recombine thereafter to reconstitute the queue of now membrane- or plate covered tiles for transport to hardening.

#### *Hardening*

After membrane and/or plate covering, and optional vibration treatment, in accordance with the invention, the membrane or plate is removed or, preferably, the article is at least partially hardened with the membrane or plate still in place. The latter is preferable for two main reasons. Firstly,

attempting to peel the membrane or slide or otherwise separate the plate from the surface of the article before any significant hardening of the paste layer may disturb the smoothness of its still unhardened surface to some extent (though this may be minimised by careful removal of the membrane or plate, and by choice of membrane or plate and paste layer surface characteristics which minimise adhesion of the membrane to the paste layer). Surface smoothness damage is increasingly less likely as the paste layer hardens. Secondly, the membrane or plate protects the treated surface from damage during or after handling. In fact, it may be desirable in the case of tile manufacture to keep the membrane (less desirably the plate) in place until the point of end use, for this very reason.

#### *Special Effects*

When the optional vibrational step is employed in the process of the invention, a dry, particle-containing composition may be applied to the surface of the paste layer prior to its being covered by the membrane and/or plate. The vibrational treatment then causes the particles of that composition to become embedded in the vibrated surface of the paste layer. Particles such as colour pigment, silicate granules, metal, or polymer particles may be incorporated in this way.

The principles of the invention will now be further discussed by reference to the following Drawings (which are not to scale), wherein

Fig 1A is a simplified perspective view of an assembly consisting of a flat tile with a paste layer spread on its upper surface, a flexible membrane or plate covering the entire area of the paste layer.

Fig. 1B is a schematic longitudinal cross-sectional view of the assembly of Fig 1A.

Fig. 1C shows in schematic cross-section how a membrane may be laid to cover the spread paste layer to produce the assembly of Fig 1A.

Fig. 1D shows in schematic cross-section how a plate may be laid to cover the spread paste layer to produce the assembly of Fig 1A.

5 Fig.2A shows in schematic cross-section how a paste layer may be spread on a tile or tile ribbon by spraying.

Fig 2B shows in schematic cross-section how a paste layer may be spread on a tile or tile ribbon by curtain deposition from a flow guide tool.

10 Fig.2C shows in schematic cross-section how a paste layer may be spread on a tile by squeezing a portion of paste deposited on the tile between the tile and a membrane as the latter is rolled onto the paste portion.

15 Fig 2D shows in schematic cross-section how a paste layer may be spread on a tile by squeezing a portion of paste deposited on the tile between the tile and a plate as the latter is pressed onto the paste portion.

Fig 2E shows in schematic cross-section how a paste layer may be spread on a tile by spattering from a roller.

20

Referring to Figs 1A and 1B, numeral 1 indicates (a) a plain, generally flat clay or cementitious roofing tile, or (b) an unhardened water-containing clay or cementitious mass moulded in mould 2 (shown in Fig 1B, but omitted for clarity in Fig 1A) into the form of a plain, generally flat roofing tile, or (c) a section of a continuous ribbon of unhardened water-containing clay or cementitious mass from which tile forms (b) may be cut. A paste layer 3 is spread on the upper surface of the tile, tile form or ribbon. Numeral 4 indicates a flexible membrane, for example of polyethylene or polypropylene or paper-based material, or a plate of, for example, acrylic plastics or steel, covering the upper surface of the paste layer and lying in intimate contact with that surface. The membrane or plate has a smooth under-surface in contact with the paste layer, and is sized to cover the area of the paste layer, possibly with marginal overhangs.

30

An optional resiliently mounted vibrator head 5 of the same width as the tile, tile form or ribbon 1, vibrating, for example, at about 20kHz mainly in the plane perpendicular to the plane of the paste layer, may be pressed into contact with the upper surface of the membrane or plate. In a variation, a membrane may be in contact with the paste layer, a plate may be superimposed on the membrane, and the vibrator head may contact the plate. The vibrator head is movable, while still in pressure contact with the membrane or plate, in the direction indicated by arrow A, to traverse the entire length of the tile, tile form or ribbon. The vibrating head traverses the length (and thus the area) of the membrane- or plate-covered paste layer. That process may be optionally repeated as many times as desired, or multiple vibrator heads may be arranged to traverse the membrane- or plate-covered paste layer sequentially. Multiple vibrator heads or multiple vibrator head passage passage, allows the paste layer to be vibrated at different frequencies. After vibration, the head is lifted out of contact with the membrane or plate.

The membrane- and/or plate-covered tile or tile form (after optional vibration treatment) is transported for the paste layer (and the unhardened tile form if still unhardened at this stage) to be at least partially hardened at ambient temperature, or in an oven. The membrane or plate may be removed from the paste layer after partial or substantially complete hardening, or later.

In Fig. 1C, a hardened or unhardened tile 11 having a paste layer 12 spread over its upper surface is being conveyed in the direction of arrow A. A roll of membrane feedstock 13 having a smooth under-surface is positioned to dispense a continuous sheet of membrane material onto and into intimate contact with the surface of the paste layer, via a membrane application roller 14 which is in slight pressure contact with the paste layer (although for clarity, the roller and membrane are drawn out of contact with the paste layer). When the passage of the tile 11 past the application roller 14 has covered the paste layer with membrane, a knife tool (not show) cuts the membrane across the tile width to allow the membrane covered tile to pass downstream for the paste layer hardening stage.

( In Fig. 1D, a hardened or unhardened tile 21 having a paste layer 22 spread over its upper surface is being conveyed in the direction of arrow A. As the tile is conveyed the paste layer slides under and into intimate contact with the smooth under-surface of a flat steel or acrylic plate 23 (although again for clarity, the plate is drawn out of contact with the paste layer). Smooth sliding of the tile under the plate is assisted by the slightly curved configuration of the front end 24 of the plate. The plate is maintained in a fixed position by a plate holding and release mechanism (not shown). When the passage of the tile 21 under the plate has positioned the plate so that it covers the paste layer, the plate is released by the plate holding and release mechanism and the plate-covered tile passes downstream for the paste layer hardening stage.

In Fig.2A, numeral 31 indicates (a) a hardened tile, or (b) an unhardened water-containing clay or cementitious mass carried in a mould or pallet (not shown) in tile format, or (c) a section of a continuous ribbon of unhardened water-containing clay or cementitious mass from which tile forms (b) may be cut. A layer 32 of paste of sprayable consistency is sprayed from spray head 33 onto the upper surface of the tile, or unhardened tile form or ribbon. The paste layer is built up by passage of the tile, tile form or ribbon past the spray head in the direction of arrow A. More than one spray head might be employed.

In Fig 2B numeral 31 has the same significance as in Fig 2A. Paste 44 of flowable consistency flows from storage hopper 43 over the surface of a suitably shaped flow guide tool 45, and is deposited as a curtain to form a layer 46 on the upper surface of the tile, or unhardened tile form or ribbon as it passes under the flow guide in the direction of arrow A.

In Fig 2C numeral 31 has the same significance as in Fig 2A. As in Fig 1C, a membrane feedstock 52 having a smooth under-surface is dispensed via a membrane application roller 53. A portion of paste 54 was previously deposited as a strip across the width of the tile, tile form or ribbon 31 at its leading edge as it moves in direction of arrow A, or in the case of a ribbon at spaced intervals across its width. As the paste portion encounters the

membrane application roller, it is squeezed between the membrane being unwound from the roller and the tile, tile form or ribbon, causing it to be spread as a paste layer 55, covered by the membrane.

- 5 In Fig 2D numeral 31 has the same significance as in Fig 2A. As described in relation to Fig 2C, a portion of paste 64 was previously deposited as a strip or strips across the width of the tile, tile form or ribbon 31. A plate 65 is pivotally positioned at an acute angle to the plane of the tile, tile form or ribbon. Initially the plate 65 and paste portion 64 are in a positional relationship similar to  
 10 those shown by broken lines. The angle between the plate and the tile, tile form or ribbon is then reduced by rotating the plate about its lower edge, through a relative position similar to that shown by the continuous lines depicting plate 65 and paste portion 64, until the plate lies parallel to the surface of the tile, tile form or ribbon, spaced therefrom by a thickness  
 15 corresponding to the desired depth of paste layer. This has the effect of squeezing the paste portion between the plate and the tile, tile form or ribbon, causing it to be spread as a paste layer, covered by the plate.

- In Fig 2E numeral 31 has the same significance as in Fig 2A. Paste 74 of  
 20 flowable consistency flows from storage hopper 73 onto a roller 72 rotating clockwise. A stiff brush roller 71 rotates counter clockwise and is positioned longitudinally adjacent the roller 72. as the paste carried on roller 72 encounters the rotating brush 71, the brush sweeps the paste from the roller and throws it as a shower onto the surface of the tile, tile form or ribbon as it is  
 25 conveyed in the direction of arrow A, thereby building up the desired paste layer 75.

- The above discussion of Figs 1A-1D and Figs 2A-2E have been in relation to plain flat tiles of substantially rectangular cross section. For many roofing  
 30 applications, the tiles have a contoured cross section, for example a substantially S-shaped contour. The principles discussed in relation to flat tiles are equally applicable to contoured tiles, with appropriate contouring of any membrane application rollers, paste flow guide tools, paste layer cover plates, vibrator heads and the like. Similarly, the principles discussed are generally

applicable to other clay, cementitious, or ceramic articles, with appropriate matching of size and contour of the elements of the process to the size and shape of the article.

## Claims

1. A method for the surface treatment of a clay, ceramic or cementitious article comprising

5

(i) providing a hardened or partially hardened clay, ceramic or cementitious article, or a hardenable, water-containing clay, ceramic or cementitious mass shaped in the form of the article,

10 (ii) spreading a layer of eventually hardenable paste over a surface area of the article or shaped mass to be treated, the paste comprising at least first and second populations of particles co-dispersed in a water-containing phase, the second population being sufficiently small to pack the interstices between particles of the first population with which it is co-dispersed, at least one of the  
15 first and second populations being of reactive binder particles,

(iii) covering a surface area of the paste layer with (a) a flexible membrane or (b) a plate or (c) first a flexible membrane then superimposed thereon a plate, the plate or membrane having an upper-surface and a smooth under-surface,  
20 such that in cases (a) and (c) the smooth membrane under-surface, and in case (b) the smooth plate under-surface, is in intimate contact with and conforms to the contours of that surface area of the paste layer, thereby providing a membrane-covered or plate-covered area of the paste layer,

25 (iv) optionally vibrating the membrane-covered or plate-covered area of the paste layer, such that vibration is transmitted through the membrane or plate, to the paste layer, and

(v) either removing the membrane, plate or plate and membrane then  
30 hardening the paste layer on the article or shaped mass, or at least partially hardening the paste layer on the article or shaped mass with the membrane, plate or plate and membrane in place.

2. A method as claimed in claim 1 wherein in step (ii) one or more portions of paste is/are positioned on the article or shaped mass and spread as the desired layer by causing the membrane or plate to be pressed into contact with the portion(s) during the covering step (iii), thereby causing the portion(s) to spread as the desired paste layer between the under-surface of the membrane or plate and the article or shaped mass.

3. A method as claimed in claim 1 or claim 2 wherein the membrane or plate is pressed into intimate contact with the paste layer by rolling pressure applied to the membrane or plate or by reduced atmospheric pressure between the membrane or plate and the paste layer.

4. A method as claimed in any of the preceding claims wherein the surface of the article or shaped mass is treated prior to spreading the paste layer, to improve binding between it and the paste layer.

5. A method as claimed in any of the preceding claims wherein the flexible membrane is of plastics or paper-based material or the plate is of plastics material or metal.

6. A method as claimed in any of the preceding claims wherein the the first population has a weight average particle size in the range  $1\mu\text{m}$  to  $200\mu\text{m}$  and the second population has a number average particle size from  $0.001\mu\text{m}$  to  $20\mu\text{m}$ .

7. A method as claimed in claim 6 wherein the first population is of reactive binder particles, e.g. cement, and/or fly ash and/or blastfurnace slag particles and the second population is of binder particles e.g. microsilica, blastfurnace slag powder or fly ash or of non-binder particles e.g. iron oxide.

8. A process as claimed in claim any of the preceding claims wherein in the paste additionally comprises a population of aggregate particles having a weight average particle size in the range 100 $\mu$ m to 500 $\mu$ m, and/or a population of micro-aggregate particles having a weight average particle size in the range 0.01 $\mu$ m to 50 $\mu$ m and/or a population of micro-fibres having a mean length in the range 100 $\mu$ m to 1mm.

9. A method as claimed in any of the preceding claims wherein the paste is degassed or mixed to minimise entrained gas bubbles prior to being spread on the article or shaped mass.

10. A method as claimed in any of the preceding claims wherein the paste layer on the article or shaped mass is hardened or partially hardened with the membrane, plate or plate and membrane in place, and then the membrane, plate or plate and membrane is separated from the hardened or partially hardened paste layer.

11. A method as claimed in any of the preceding claims wherein the article is, or the mass is shaped in the form of, a roofing tile, a wall tile, a floor tile, a roofing panel, a pipe, a work-top, a paving block or a wall cladding panel.

12. A method as claimed in any of the preceding claims wherein in step (ii) a membrane is contacted with the paste layer, and the vibrational step (iv) is implemented by vibrating the paste layer through the membrane by pressing into intimate contact an area of the membrane-covered area of the paste layer and a membrane-contact surface of a vibratable plate element contoured to match that of the membrane-covered area of the paste layer, and causing the vibratable plate element to vibrate while maintaining pressure contact between it and the membrane-covered area of the paste layer, such that vibration is transmitted from the vibratable plate element, through the membrane, to the surface of the paste layer.

13. A method as claimed in any of claims 1 to 11 wherein in step (ii) a plate is contacted with the paste layer, or a membrane is contacted with the paste layer and a plate is superimposed thereon, and the vibrational step (iv) is implemented by pressing a vibrating head element into intimate contact with an area of the plate-covered area of the paste layer, and causing the head element to vibrate while maintaining pressure contact between it and the plate-covered area of paste layer, such that vibration is transmitted through the plate element to the paste layer.

14. A method as claimed in claim 12 or claim 13 wherein the plate is vibrated by contacting a vibrating head element with the side of the plate opposite the paste layer, and causing relative movement between the head element and the contacted plate and membrane-covered area of the paste layer, such that the vibrating head element traverses a desired area of that side.

15. A method as claimed in claim 14 wherein the vibratable plate element is rectangular with uniform transverse cross sectional profile, the vibrating head element is contoured to match that profile, and the head is caused to move longitudinally relative to the plate.

16. A method as claimed in any of claims 12 to 15 wherein the axis or main axis of vibration of the surface of the paste layer of the article is generally perpendicular to that surface.

17. A method as claimed in any of claims 12 to 16 wherein vibration of a frequency of at least 150 Hz is transmitted to the surface of the article.

18. A process as claimed in any of claims 12 to 17 wherein the frequency and amplitude of the vibration and the duration of the vibration are selected to increase the surface density of paste layer, relative to its density prior to vibration, to a depth of at least 10% of its thickness.

19. A process as claimed in any of claims 12 to 17 wherein the frequency and amplitude of the vibration and the duration of the vibration are selected to increase the surface density of the paste layer, relative to its density prior to vibration, to a depth of at least 25% of its thickness.

5

20. A process as claimed in any of claims 12 to 17 wherein the frequency and amplitude of the vibration and the duration of the vibration are selected to increase the surface density of the paste layer, relative to its density prior to vibration, to a depth of at least 50% of its thickness.

10

21. A process as claimed in any of claims 12 to 17 wherein the frequency and amplitude of the vibration and the duration of the vibration are selected to increase the density of the paste layer throughout its entire thickness.

15

22. A process as claimed in any of claims 12 to 21 wherein the vibration transmitted through the plate or plate and/or membrane has a frequency in the range 15 kHz to 50 kHz.

20

23. A process as claimed in any of claims 12 to 22 wherein the vibration transmitted through the plate or plate and/or membrane has a frequency in the range 15 kHz to 30 kHz.

25

24. A process as claimed in any of claims 12 to 23 wherein the vibration transmitted through the plate or plate and/or membrane has an amplitude in the range 1 mm to 3 $\mu$ m.

30

25. A process as claimed in any of claims 12 to 24 wherein the vibration transmitted through the plate or plate and/or membrane varies in frequency and/or amplitude.

26. A method as claimed in any of claims 12 to 25 wherein a dry, particle-containing composition is applied to the surface of the paste layer prior to its being covered by the membrane.

27 A method as claimed in claim 26 wherein the particles in the particle-containing composition are colour pigment, silicate granules, metal, or polymer particles.

5

28. A method as claimed in any of the preceding claims wherein a relief-pattern is formed on the paste layer contact surface of the membrane or plate or interposed between the plate and a membrane-covered area of the article, such that when the plate is pressed into contact with the membrane-covered  
10 area of the article and/or vibrated the relief pattern impresses the surface of paste layer.

29. A method as claimed in any of claims 1 to 28 wherein a membrane is in contact with the paste layer and a relief-pattern is impressed into the surface  
15 of the paste layer by a tool pressing the upper surface of the membrane when in contact with the paste layer.

30. A process as claimed in any of the preceding claims wherein the article or the hardenable mass on which the paste layer is cementitious containing  
20 cement particles and microsilica particles as reactive binder particles.

31. A process as claimed in claim 30 wherein the article or the hardenable mass contains sand.

25 32. A method as claimed in any of the preceding claims for production of cementitious tiles for roofing or wall cladding, wherein in step (I) a an at least partially hardened tile or hardenable water-containing cementitious mass shaped in the form of a tile is provided by

30 (a) providing a mouldable, eventually hardenable mass comprising at least water and reactive binder particles, the latter including at least cement particles,

(b) extruding the mass from an extrusion orifice onto conveyor means adapted to carry the extruded mass as a ribbon away from the

extrusion orifice, the ribbon having a lower surface in direct or indirect contact with the conveyor means and an upper surface,  
 (c) cutting the pressed, ribbon across its width into individual tile format  
 and  
 5 (d) optionally at least partially hardening the individual tiles.

and wherein the paste layer is spread after steps (a) and (b) or after steps (a) to (c) or after steps (a) to (d).

10 33. A method as claimed in claim 32 wherein the conveyor means is provided with a plurality of longitudinally closely adjacent pallets or moulds of individual tile dimensions onto which the ribbon is extruded, and the ribbon is cut into individual tiles across its width between adjacent pallets of moulds.

15 34. A method as claimed in claim 33 wherein the base of a pallet or moulds on the conveyor belt has a smooth surface to function as a plate in step (iii) or may be lined with a smooth surfaced membrane to function as a plate covered membrane in step (iii), paste is deposited on the said smooth base or  
 20 membrane, and the ribbon is deposited or pressed onto said base or membrane whereby the paste is spread as a layer on the underside of the tile.

35. A method as claimed in any of claims 32 to 34 wherein, the conveyor means divides into a plurality of tracks after the ribbon is cut into individual tiles, tiles queued on the conveyer are successively transported onto separate  
 25 tracks for the application of individual membrane or plate covers and/or optional vibrational treatment on each tile at individual stations associated with each track, and the tracks recombine thereafter to reconstitute the queue of tiles for transport to hardening.
